Science driver: The expansion of the universe is accelerating, but we know almost nothing about the mechanism – “Dark Energy”

What causes cosmic acceleration?

Three possibilities:

1. The universe is filled with a negative-pressure component that gives rise to 'gravitational repulsion': **Dark Energy**
2. The theory of General Relativity (gravity) is wrong on cosmic distance scales
3. The universe is inhomogeneous and only apparently accelerating, due to large-scale structure (unlikely given current data)

Path to the greatest prize in physics:
Reconciliation of gravity and quantum mechanics.

Gravitational lensing traces mass structure vs cosmic time
– A promising dark energy probe that is sensitive to both structure growth and geometry

The Large Synoptic Survey Telescope (LSST) will be a primary dark energy instrument in the next decade

The LSST gravitational lensing measurement of dark energy is systematics limited

- DOE/NSF project
- 3.2Gpix camera
- 2π steradians
- 10 sq. deg. FOV
- 30 sec visits every night for 10 years
- 15Tb / night
- Commissioning start: FY20
- 15-years of LLNL contributions

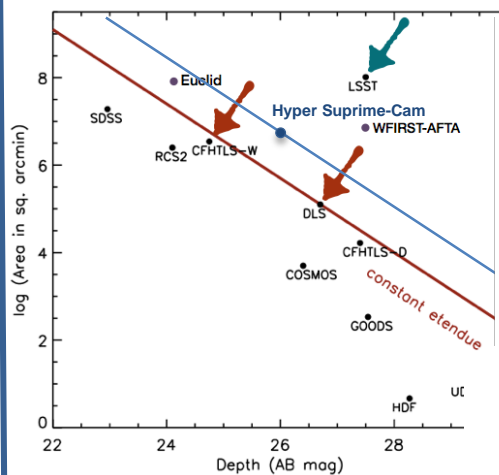

Image systematics must be controlled at this level

4 billion galaxy images

Weak lensing of galaxies: the forward model

Galaxies: Intrinsic galaxy shapes to measured image:

Image credit: GREAT08, Bridle et al.

Intrinsic galaxy
(shape unknown)

Gravitational lensing
causes a *shear (g)*

Want this

Atmosphere and telescope
cause a convolution

Detectors measure
a pixelated image

Image also
contains noise

Marginalize

Stars: Point sources to star images:

Intrinsic star
(point source)

Atmosphere and telescope
cause a convolution

Detectors measure
a pixelated image

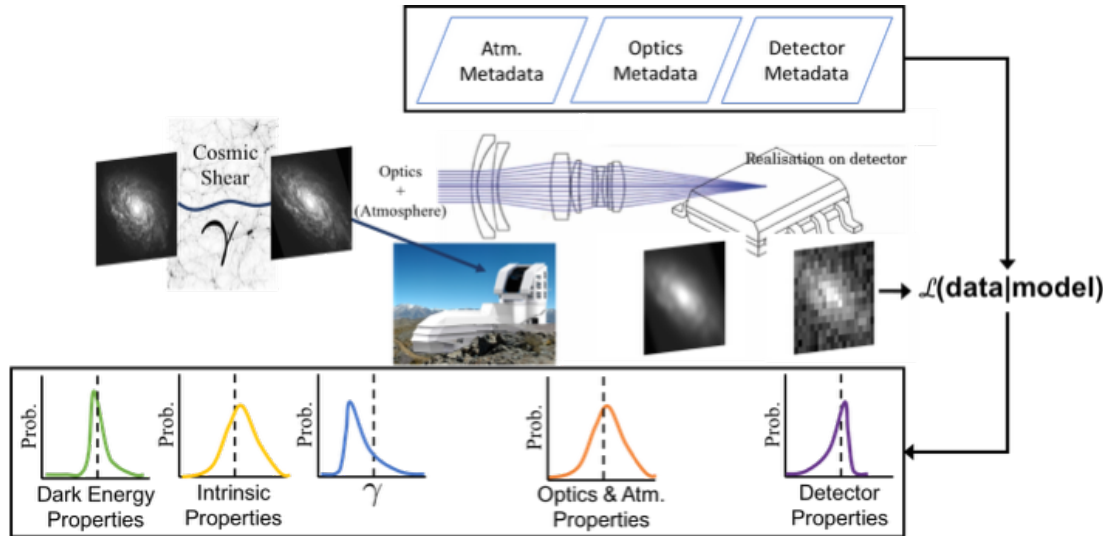

Image also
contains noise

Constrained by

Unknown &
dominates
signal

Our solution: Hierarchical Bayesian forward models of the image data

The forward model of our galaxy image data

A simplified probabilistic graphical model for galaxy image data with cosmic shear, g

The complete statistical model for cosmic shear

arXiv:1411.2608

Precision control of systematics via forward modeling and marginalization

2) PSFs 3) Cosmology

Parameter	Description
θ	Cosmological parameters
Ψ^{IC}	Initial conditions for the 3D gravitational potential
Ψ^{LT}	Late-time 3D gravitational potential
ψ_s	2D lens potential (given source photo- z bin s)
A_s	Parameters for the line-of-sight source distribution
$\Pi_{n_s,i}$	PSF for galaxy n_s observed in epoch i
Ω_i	Observing conditions in epoch i
$\{\omega_{n_s}\}$	Galaxy model parameters; $n_s = 1, \dots, n_{\text{gal},s}$
$\{\alpha_{n_s}\}$	Parameters for the distribution of $\{\omega_{n_s}\}$
$\{\xi_{n_s}\}$	Scaling parameters for $\{\omega_{n_s}\}$
m, τ	Hyperprior parameters for $\{\xi_{n_s}\}$
\mathcal{A}	Hyperparameter for $\{\alpha_{n_s}\}$ classifications
$\{\mathbf{d}_{n_s,i}\}$	Pixel data for galaxies $n_s = 1, \dots, n_{\text{gal},s}$ in epoch i
$G_0 a_\eta$	Prior specification for $\{\alpha_{n_s}\}$
s	Source sample (e.g., photo- z bin)
W	Survey window function
$\mathbf{d}_{\text{anc},i}$	Ancillary data for PSF in epoch i
p	Prior params. for observing conditions
a	Prior params. for \mathcal{A}
$\sigma_{\text{pix},i}$	Pixel noise r.m.s. in epoch i
I	Model selection assumptions

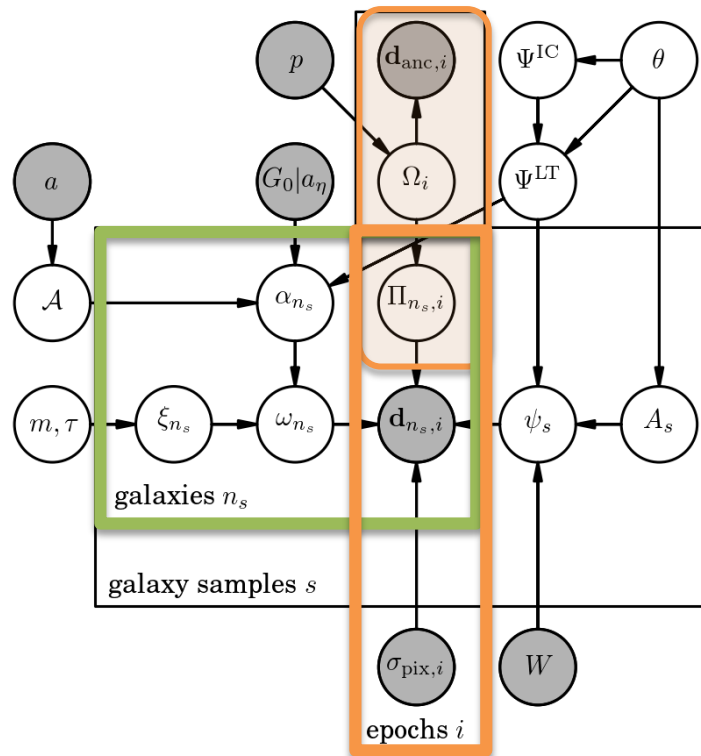

Naïve approach is intractable

1. Galaxy models be joint fitted to all available epochs i

Naïve approach is intractable

1. Galaxy models be joint fitted to all available epochs i
2. **PSF models** must be joint fitted to all galaxies in an exposure n_s

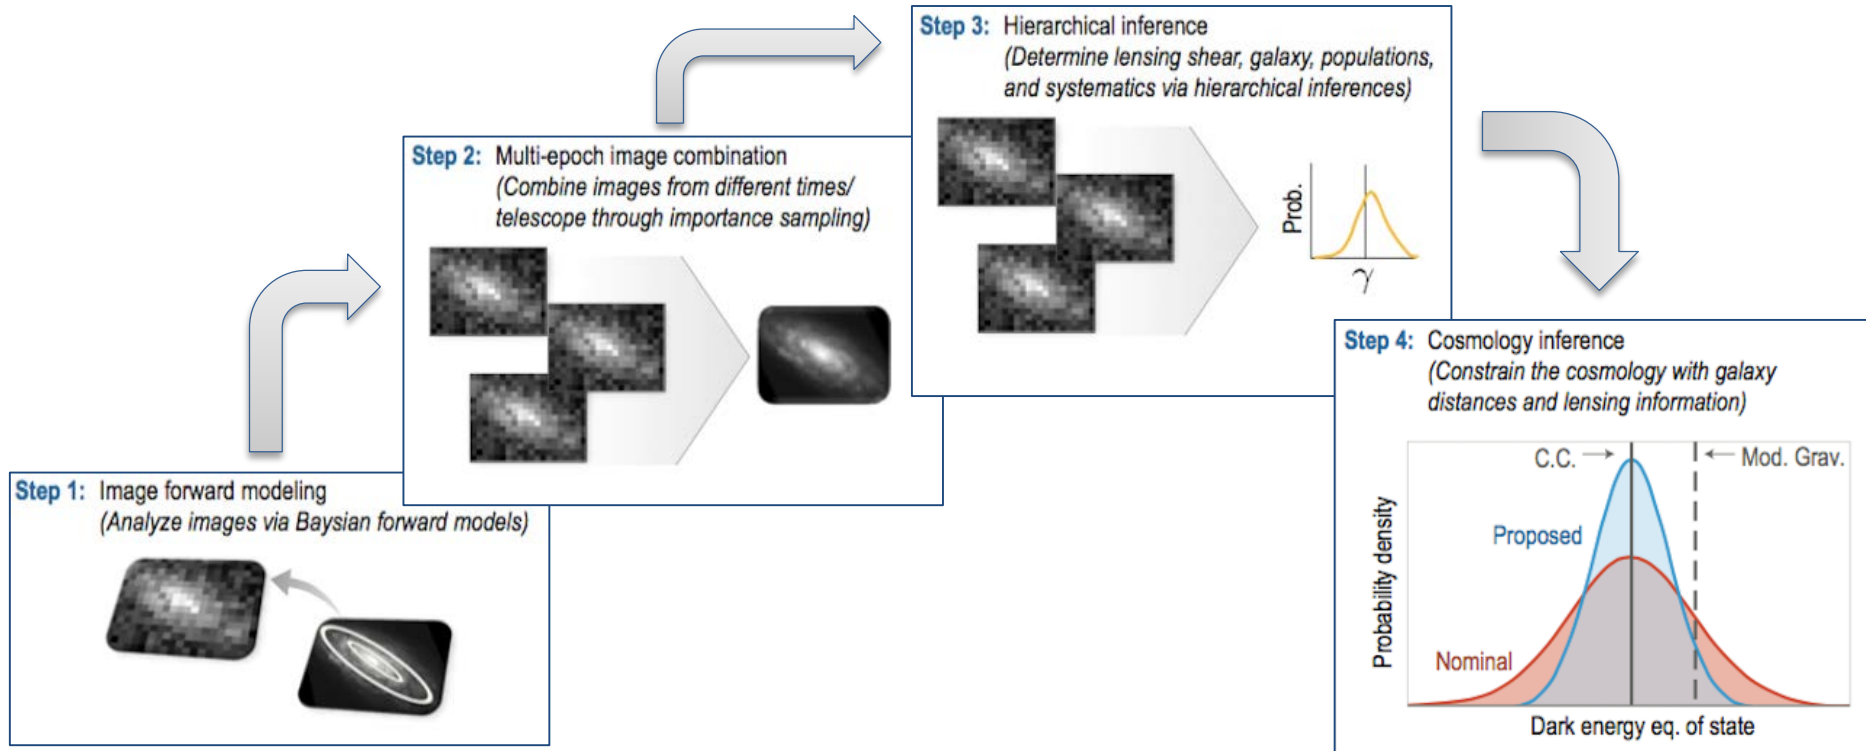

Naïve approach is intractable

1. Galaxy models be joint fitted to all available epochs i
2. PSF models must be joint fitted to all galaxies in an exposure n_s
3. **Cosmology** must be joint fitted to all galaxy samples & epochs

The principled inference requires fitting all pixels of all surveys simultaneously

We have developed a tractable 'divide & conquer' computational approach for the complete statistical model for multiple imaging surveys

Importance Sampling allows tractable divide & compute :

The pseudo-marginal likelihood

Want:

$$\Pr(\mathbf{d}|\alpha) \propto \prod_{n=1}^{n_{\text{gal}}} \int d\omega_n \underbrace{\Pr(\omega_n|\alpha)}_{\text{Galaxy dist.}} \underbrace{\Pr(\mathbf{d}_{n,i}|\omega_n)}_{\text{Likelihood}}$$

Have samples from:

$$\Pr(\omega_n|\mathbf{d}_n, I_0)$$

‘Interim prior’
specification

Importance sampling:

$$\Pr(\mathbf{d}_n|\alpha) \approx \frac{Z_n}{K} \sum_k \frac{\Pr(\omega_{nk}|\alpha)}{\Pr(\omega_{nk}|I_0)},$$

$$\Pr(\mathbf{d}|\alpha) = \prod_{n=1}^{n_{\text{gal}}} \Pr(\mathbf{d}_n|\alpha).$$

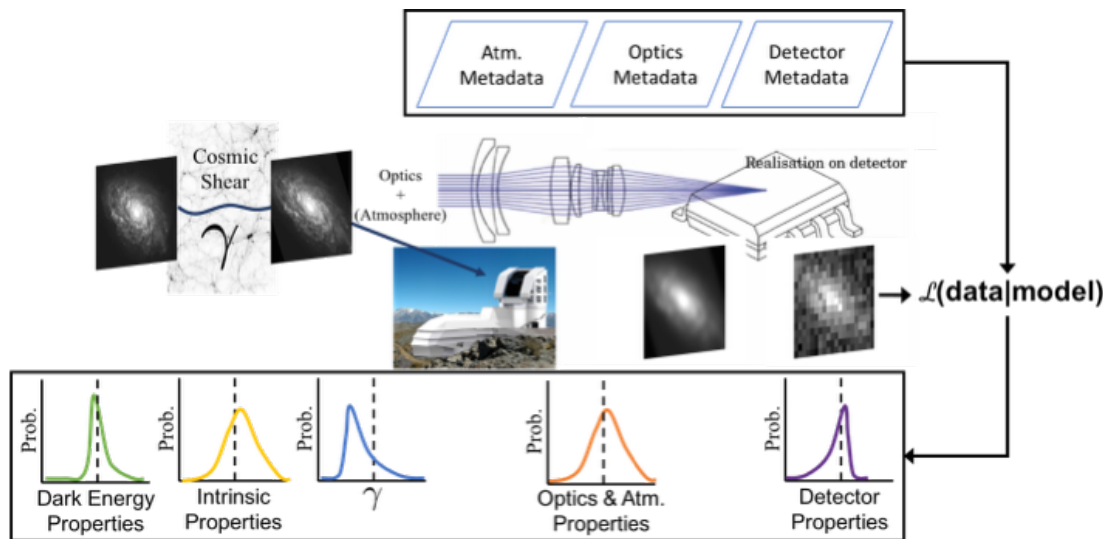

Ongoing research question:
How many interim samples are needed?

Credit: J. Meyers

Our hierarchical Bayesian forward models can meet LSST systematics tolerances for galaxy shear when the model is accurate enough

The forward model of our galaxy image data

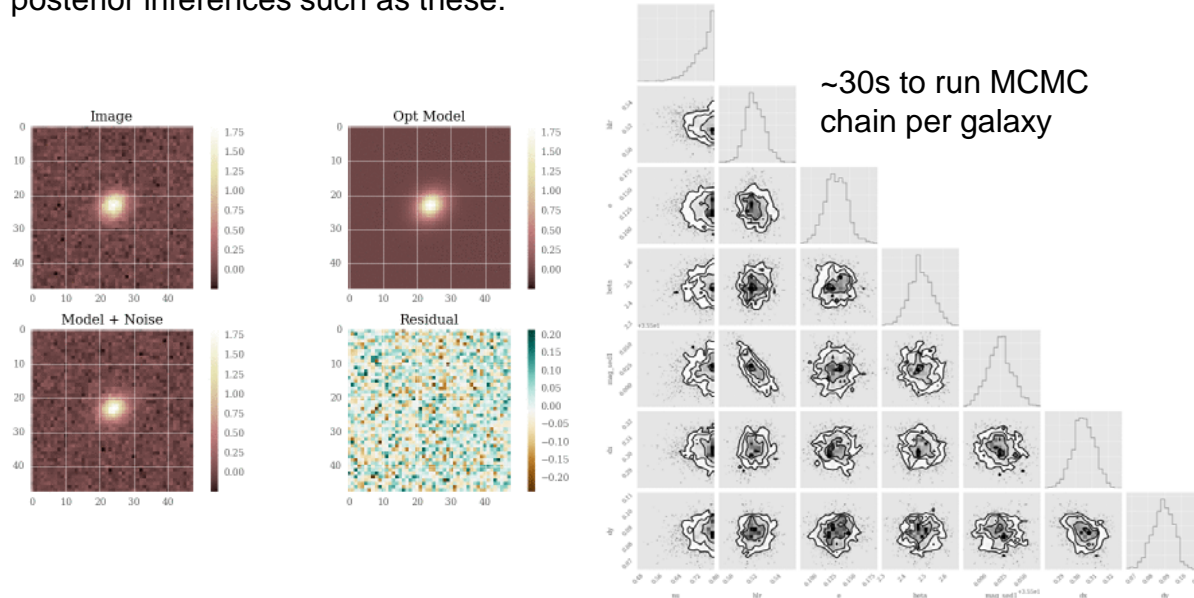

Our approach works:

Sensitivity analyses with (simplified) galaxy simulation suites show biases well below LSST tolerances

Accurate modeling in an MCMC framework is more computationally demanding than traditional approaches – but still tractable

Every data point on the right is inferred from thousands of galaxy image model posterior inferences such as these:

Our approach works:

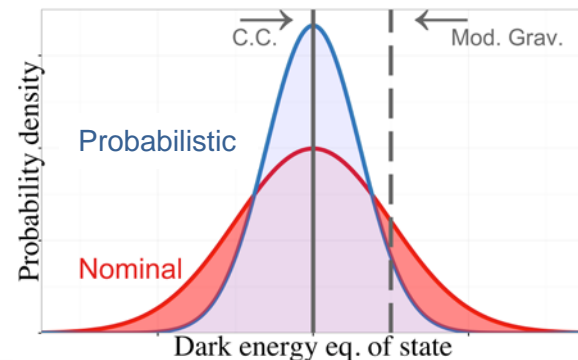

Sensitivity analyses with (simplified) galaxy simulation suites show biases well below LSST tolerances

LSST data volume: 4 billion galaxies, each seen 1000 times

Summary

- Cosmic shear is systematics limited & signal is dominated by PSF and astrophysics
 - A probabilistic approach is warranted to infer a small signal and mitigate biases
- A hierarchical probabilistic model for cosmic shear can trade bias for variance, but also can increase precision by learning latent structure in the galaxy distribution.
- Importance sampling methods allow tractable approaches to a probabilistic forward model of LSST & WFIRST imaging
 - With billions of galaxies and hundreds of epochs per galaxy modeling LSST or WFIRST imaging requires an approach to separating analyses of data subsets, even though statistically correlated
- We are able to sample from a probabilistic model with multiple hierarchies to marginalize both correlated image systematics and astrophysical properties of galaxies.

The probabilistic weak lensing workflow plan for LSST

How do we combine multiple observations of the same galaxy?

Naïvely we must joint fit all epochs simultaneously

Problem: Imagine we have fit pixel data from LSST year 1.

How do we incorporate year 2 observations without redoing (expensive) calculations?

Solution: Consider single-epoch samples as draws from a multi-modal importance sampling distribution:

arXiv:1511.03095

Generalized Multiple Importance Sampling

Elvira, Martino, Luengo, & Bugallo

Multiple importance sampling (MIS) via weighted pseudo-marginals

1. Sample from the conditional posterior for each epoch individually
2. Evaluate the ratio of the conditional posterior for each epoch i to that of the MIS sampling distribution

'cross-pollination' needed:

Evaluate the likelihood of epoch i given model parameter samples from epoch j , for all combinations of i, j .

A standard scatter / gather operation

Multiple importance sampling enables streaming data analysis

Efficiency is significantly enhanced by using old data as a sampling 'prior'

- Draw parameter samples from first epoch under a nominal interim prior
- Draw samples from subsequent epochs with a prior informed by previous epoch samples
- Simulation studies show:
 - ~10% of samples have significant weight when combining 200 epochs in streaming fashion

Probabilistic cosmological mass mapping

Interpolate the unobserved lensing potential with GP

$$\psi_s \sim GP(0, \Sigma),$$

$\kappa, \gamma_1, \gamma_2$ are the second (spatial) derivatives of ψ_s

$$\text{Cov}(\psi_{,ij}(\vec{x}), \psi_{,kl}(\vec{y})) = \Sigma_{,x_i x_j y_k y_l}(\vec{x}, \vec{y}).$$

GP kernels of $\kappa, \gamma_1, \gamma_2$ are linear combinations of the 4th (spatial) derivatives of the kernel of ψ_s

Zero E/B mode mixing by construction

Objective: infer the 3D gravitational potential of the initial conditions

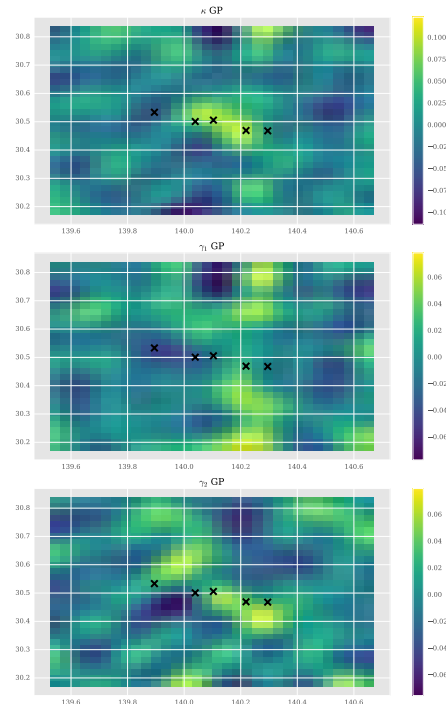

Hierarchical inference of cosmological lensing mass distributions

Validation with simulations

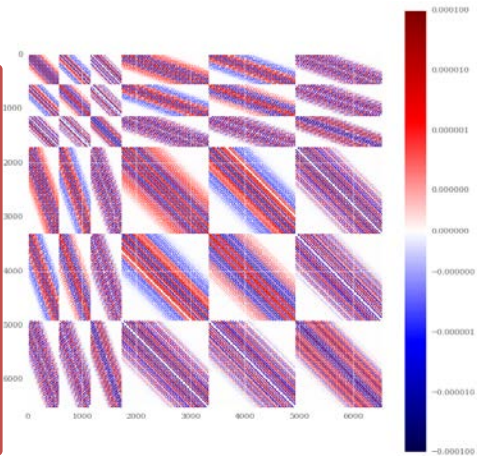

A real merging galaxy cluster

New:

- Linear and nonlinear scales reconstructed in one framework
- No E/B mode mixing by construction

Marginalizing PSFs: MIS makes this tractable

- LSST will have ~ 200 epochs per object per filter
 - We aim to marginalize the PSF $\prod_{n,i}$ in every epoch
 - The marginalization is constrained by:
 - Consistency of PSF realizations over the focal plane for each epoch
 - Consistency of the underlying source model across epochs
- Simplest approach (statistically, not computationally): Infer galaxy models given all epoch imaging simultaneously
 - “Interim” samples are of size: ~ 10 galaxy params + $200 * \sim 4$ PSF params = $\sim 1k$ parameters!
